

## **Experiment No. 5**

**Title:** Vlab on Message Authentication Codes

**Batch: A3****Roll No.: 16010421073****Experiment No.: 5****Title:** Illustrate and implement message authentication code.**Resources needed:** Windows/Linux OS**Theory:**

In cryptography, a cipher block chaining message authentication code (CBC-MAC) is a technique for constructing a message authentication code (MAC) from a block cipher. The message is encrypted with some block cipher algorithm in cipher block chaining (CBC) mode to create a chain of blocks such that each block depends on the proper encryption of the previous block. This interdependence ensures that a change to any of the plaintext bits will cause the final encrypted block to change in a way that cannot be predicted or counteracted without knowing the key to the block cipher.

**Figure 1 - CBC-MAC construction**

To calculate the CBC-MAC of message  $m$ , one encrypts  $m$  in CBC mode with zero initialization vector (IV) and keeps the last block. The figure 1 sketches the computation of the CBC-MAC of message comprising blocks  $m_1, m_2, \dots, m_x$  using a secret key  $k$  and a block cipher  $E$ .

**Activity :**

- 1) Perform the Vlab on MAC - <https://cse29-iiith.vlabs.ac.in/exp/message-authentication-codes/index.html>
- 2) Implement the similar vlab simulation with a simple block cipher in CBC mode with following details-
  - Plain text message  $M$  = user's choice (string type)
  - Block Size = user's choice (must be  $< (\text{length of } M_2)/2$ )
  - Key  $k$  = user's choice (length of key is same as block size)
  - IV = user's choice (length of IV is same as block size)
  - $E$  = XOR function

**Results:****Vlab Output:**

Plaintext:

Key, k:

length of Initialization Vector (IV), 1,  where  $1 < (\text{the length of plaintext above})/2$

IV:

Put your text of size 1 to get the corresponding value of  $F_k(\text{text})$  of size 1.

Your text:

Function output:

Final Output:

## HTML Code:

```
body {
    font-family: Arial, sans-serif;
    text-align: center;
}

h1 {
    color: #333;
}
```

```
.input-section {
    margin-top: 20px;
    border: 1px solid #ddd;
    padding: 20px;
    max-width: 400px;
    margin: 0 auto;
    background-color: #f9f9f9;
}
```

```
input[type="text"], input[type="number"] {  
    width: 100%;  
    padding: 10px;  
    margin: 5px 0;  
    border: 1px solid #ccc;  
    border-radius: 4px;  
}
```

```
button {  
    background-color: #007bff;  
    color: #fff;  
    padding: 10px 20px;  
    border: none;  
    border-radius: 4px;  
    cursor: pointer;  
}
```

```
button:hover {  
    background-color: #0056b3;  
}
```

```
.output-section {  
    margin-top: 20px;  
}
```

```
#encrypted-message {
```

```
font-weight: bold;  
}
```

#### CSS CODE

```
body {  
  font-family: Arial, sans-serif;  
  text-align: center;  
}  
  
h1 {  
  color: #333;  
}  
  
.input-section {  
  margin-top: 20px;  
  border: 1px solid #ddd;  
  padding: 20px;  
  max-width: 400px;  
  margin: 0 auto;  
  background-color: #f9f9f9;  
}  
  
input[type="text"], input[type="number"] {  
  width: 100%;  
  padding: 10px;  
  margin: 5px 0;  
  border: 1px solid #ccc;  
  border-radius: 4px;  
}  
  
button {  
  background-color: #007bff;  
  color: #fff;  
  padding: 10px 20px;  
  border: none;  
  border-radius: 4px;  
  cursor: pointer;  
}  
  
button:hover {  
  background-color: #0056b3;  
}
```

```
.output-section {
  margin-top: 20px;
}

#encrypted-message {
  font-weight: bold;
}
```

## Output:

### CBC Block Cipher Simulation

### Message Authentication Code (CBC-MAC)

**SECOND PART OF THE EXPERIMENT**

Select the option you would use to make CBC-MAC secure

Prepend the message with its length ▾

Plaintext:

Your Plaintext:

Key:

length of Initialization Vector (IV), 1,  where  $1 < (\text{the length of plaintext above})/2$

IV:

Put your text of size 1 to get the corresponding value of  $F_k(\text{text})$  of size 1.

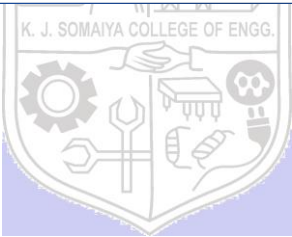

---

Put your text of size 1 to get the corresponding value of  $F_k(\text{text})$  of size 1.

Your text:

Function output:

Final Output:

### Questions:

#### 1) Compare MAC and cryptographic Hash functions.

**Ans:**

MAC (Message Authentication Code) and cryptographic hash functions are both used in cryptography, but they serve different purposes and have distinct characteristics. Here's a comparison of the two:

#### 1. Purpose:

- **MAC (Message Authentication Code):** MAC is primarily used for ensuring the integrity and authenticity of a message. It is used to verify that a message has not been tampered with and that it was indeed generated by a specific sender.

- **Cryptographic Hash Function:** Cryptographic hash functions are used to transform data into a fixed-size output (hash) in a way that is difficult to reverse. They are commonly used for data integrity checks, digital signatures, and password storage.

#### 2. Key Usage:

- **MAC:** MAC requires a secret key to generate and verify the authentication code. Both the sender and the receiver must possess the same secret key.

- **Cryptographic Hash Function:** Hash functions do not require a key; they produce a hash based solely on the input data. Hash functions are one-way functions, meaning you can't reverse them to obtain the original data.

### 3. Verification:

- **MAC:** Verification of a MAC involves re-computing the MAC on the received data using the same key and comparing it to the received MAC. If they match, the message is considered authentic.

- **Cryptographic Hash Function:** Hashes can't be directly verified in the same way as MACs. They are typically used for comparing the hash of received data to a known, trusted hash value to check for tampering.

### 4. Collision Resistance:

- **MAC:** MACs are designed to be collision-resistant, which means it should be computationally infeasible for an attacker to find two different messages that produce the same MAC with the same key.

- **Cryptographic Hash Function:** Cryptographic hash functions are also designed to be collision-resistant, meaning it should be computationally difficult to find two different inputs that produce the same hash value.

### 5. Output Length:

- **MAC:** The length of a MAC depends on the specific algorithm and key size. It can be variable.

- **Cryptographic Hash Function:** The output length of a cryptographic hash function is fixed. For example, SHA-256 always produces a 256-bit hash.

### 6. Examples:

- **MAC:** HMAC (Hash-based Message Authentication Code) is a widely used MAC algorithm.

- **Cryptographic Hash Function:** Examples include SHA-256, SHA-3, and MD5 (though MD5 is not recommended for security-sensitive applications due to vulnerabilities).

---

### Outcomes:

**CO 2** Illustrate different cryptographic algorithms for security.

---

### Conclusion:

Thus, we have successfully completed the implementation of MAC and also made a simple GUI to describe it.
